

Unit 6 – Momentum and Impulse
Section 6.1: Momentum

Every moving object has momentum, which is a measure of

how scared you should be of something coming at you.

Momentum depends on velocity and mass.

"rho"

$$\vec{p} = m\vec{v}$$

momentum → \vec{p} ← velocity (m/s) ← \vec{v} ← mass (kg) ← m

What are the units of momentum?

$$\frac{\text{kgm}}{\text{s}}$$

or

N·s (Newton seconds)

Example: A 10,000 kg train is traveling at 5 m/s east.

a) What's its momentum?

$$\begin{aligned} \vec{p} &= m\vec{v} \\ &= 10,000 \text{ kg} \times 5 \text{ m/s} \\ &= 50,000 \text{ kgm/s east} \end{aligned}$$

b) How fast would a 730 kg smart car need to go in order to have the same momentum?

$$\begin{aligned} \vec{p} &= m\vec{v} \\ 50,000 \text{ kgm/s} &= (730 \text{ kg})\vec{v} \\ \frac{50,000}{730} &= \vec{v} \end{aligned}$$

68.49 m/s or 246.6 km/h

When an object experiences a net force, its momentum changes. It's often useful to calculate the

change in momentum (a.k.a. Δp)

$$\Delta = \text{final} - \text{initial}$$

Example: A bouncy ball strikes a wall at 32 m/s east and bounces back at 20 m/s west. Calculate Δp .

$$\begin{aligned} (m = 30\text{g}) \\ \text{or} \\ 0.03 \text{ kg} \end{aligned}$$

$$\Delta p = p_f - p_i$$

$$= mv_f - mv_i$$

$$= m(v_f - v_i)$$

$$= 0.03 \text{ kg}(-20 \text{ m/s} - 32 \text{ m/s})$$

$$= 0.03 \text{ kg}(-52 \text{ m/s})$$

$$= -1.56 \text{ kgm/s}$$

1.56 kgm/s west is Δp
